

Technical description of the Studera.Nu search engine

Harvesting policies, maintenance and software used

Sigfrid Lundberg, sigfrid.lundberg@lub.lu.se

NetLab,¹

Lund university, Sweden

ABSTRACT

The Studera.NU carries focused information, all of which is indexed manually by content providers. The indexing information is embedded into web pages using meta tags, and the service is built using a harvesting robot.

This article documents the functions of the search engine Studera.NU, its robot, search software etc. It aims at providing necessary background information both for staff involved in system management and future developers. A second aim is to give pinpoint areas for future developments of the service.

1 Introduction

The Studera.Nu service² aims at providing information on higher educations in Sweden structured in relation to subject and profession, and search-able by other relevant metadata. For students it should provide one-stop-shopping access distributed information produced by institutions of higher education in the country. The search engine is owned by the The Swedish Council for higher education.³

Hitherto, such information has been provided locally by universities and university colleges and published on the Internet through different means, but the same information has been made available with some variations in a central database. In practice, the costly and labour intensive cataloguing of courses and educations have performed twice. The new system allows continuous update of the data at a lower maintenance cost.

2 Searching and Metadata

2.1 The Studera.Nu Metadata element set

The metadata set for describing both the educational intellectual content and what we call events⁴ have been defined by the Council for Higher Education, with some input from

¹ <http://www.lub.lu.se/netlab/>

² Studera.Nu

<http://www.studera.nu/>

³ The Swedish Council for higher education

<http://www.hsv.se/>

⁴ Studera.Nu Metadata Element Set

<http://studera.hsv.se/internt/felt.htm>

NetLab.

The reason for using meta-tags, rather than some more fancy XML⁵ or RDF⁶ is that the necessary expertise to for implementing such export systems where not available among the content providers at the time.

An example metadata object is included in Appendix B, and the robot's interpretation of the same item in Appendix C.

2.2 Information retrieval standards used

The search engine used is Studera implements the Z39.50 information retrieval protocol⁷. To be more specific, it is using the GILS⁸ Z39.50 profile. Governmental Information Locator Service (GILS) was a of president Clinton's Information Highway, and meant to be an inter-operable method for search and retrieval of Governmental Information in general, but it has proved general enough for use in a wide range of applications. Lists of example services using . Software which supports are available on the GILS web site⁹. We have used it for years in the context of web indexing^{10 11}

The search service is compliant with the rest of the worlds view on what such a service should do. Hence it is capable of delivering search results both in the Z39.50 internal GRS1 (Generic Record Syntax 1) and the record syntax used in library world, namely MARC¹² and with BIB-1¹³ search attributes. In principle, it is thus possible for anyone to cross search Studera.NU, together with other Z39.50 services, like Libris or Safari. The only factor that makes this impossible is that the server is situated behind a fire wall.

The two hierarchical vocabularies used are also accessed using Z39.50, using the Zthesaurus profile,[not:zthes} which is meant to give access to controlled vocabularies. Using this, it is possible for providers to incorporate vocabulary support in their services without

themselves controlling or maintaining it.

2.2.1 Non-standard Z39.50 features

In general we have used the semantics of the GILS profile for assigning tag paths and search attributes to the various metadata elements used. For some of them we were forced to use shoe horn. The metadata elements in question are:

exam

uses GILS element *purpose*, with roughly the same semantics as a target audience

profession

There is nothing that can be used in the profile. We have assigned it to a local tag path, and is using the controlled term search attribute for searching. The only reason why it works, is that the controlled terms different controlled terms are different. **Should have been moved to a local search attribute for compatibility.**

prerequisites

Is using access constraints elements in GILS, i.e., it is not really the same semantics, but at least related.

The event field in the Studera.NU Element set has a value which is precoordinated string with the following formal syntax¹⁴

```

event ::= 
eventid';'period';'coursetype';'intensity';
           'location';'language';'time
eventid   ::= (Letter | Digit)*
period    ::= '20'[0-9, 0-9]'p'[1-5]
           /* year divided into five parts*/
           /* service breaks year 2100      */
coursetype ::= 'bunden' | 'flexibel'
intensity  ::= 'low' | 'medium' | 'high' | 'full' | 'flexibel'
location   ::= [0-9]+ | 'flexibel'
           /* a numeric location code or */
           /* a flexible location          */
language   ::= 'en' | 'sv'
time       ::= (Letter | Digit | [ ,.#x20])*
Letter     ::= [a-zA-Z]
Digit      ::= [0-9]
```

The value is stored as GILS orderInformation. Although the eventid is the application id of the course, this is again not the semantics that would be expected from a governmental information source.

Queries in this field is done through regexp search. A default value matching all events is

¹⁴ A simple Extended Backus-Naur Form (EBNF) notation
<http://www.w3.org/TR/1998/REC-xml-19980210#sec-notation>

```

period      20[0-9, 0-9]p[0-9];
coursetype  (sommar|bunden|flexibel);
intensity   (low|medium|high|full|flexibel);
location    [0-9, 0-9, 0-9, 0-9]|flexibel;
language    (sv|en)

```

where the components above should be combined into a single string (too long for printing on an A4 sheet):

```
period;coursetype:intensity:location:language
```

The semicolons ';' are not used by the search engine.

2.2.2 Accessing the Z39.50 server

The necessary data for querying the server for course information is:

Host	afrodite.hsv.se
Port	2100
Databases	studera (for courses and programs) and webindex (for other information)

As is mentioned below, there is another (not yet published) database available for information other than course and program. Both databases are on the same server. The webindex database is configured exactly as the studera base, but with much fewer fields available for searching. See Ardö and Lundberg (1998) for further information on the setup of a similar server¹⁵

2.2.3 Search software used

The Studera.NU is using the Zebra information server¹⁶ for searching. There are three reasons for choosing Zebra: (i) It is an extremely fast and reliable full text searching engine, with powerful handling of tagged text. It also supports incremental update of index files, a feature necessary for databases where a large fraction of the records are replaced or updated more or less daily. (ii) We have good experience of using it in combo with the robot used. (iii) It supports Z39.50, which gives a lot of features for free.

Now, in the context of the Studera.NU service, the importance of points (i) and (ii) cannot be exaggerate, whereas point (iii) is of less importance. Indeed, the data-model used contains complications that are uncommon in bibliographic searching. The problems we have experienced are not really due to the access protocol per se, but to the fact that Zebra is a full text engine, and as such it has difficulties handling the events. This would have

¹⁵ A. Ardö and S. Lundberg, 1998. A regional distributed WWW search and indexing service — the DEISRE way. Computer Networks and ISDN systems 30:173-183
<http://decweb.ethz.ch/WWW7/1900/com1900.htm>

¹⁶ Indexdata, The Zebra information server.
<http://www.indexdata.dk/zebra/>

been easy in any relational database. These difficulties have been aggravated by the fact that there are features or bugs in the regexp search in Zebra making it difficult to formulate queries correctly.

The whole suit of software used is:

Zebra server

Links and references given above. The manual is available online.¹⁷ There is one problem for the future. Zebra is open source software, but the current version does not support neither incremental update of indexes nor multiple databases. These are features which has been moved to a commercial version of the package called Z'mbol (Zebra in Swahili). If and when Z'mbol diverges from the Zebra package as before the split 1 January 2000, it might be worthwhile to acquire a commercial license.

The zebra server lives in `afrodite.hsv.se:/usr/local/studera/zebra`, while most of its library files is in `afrodite.hsv.se:/usr/local/lib/yaz/`

ZAP! Z39.50 gateway

ZAP!¹⁸ is an Apache module, i.e., it makes searching a built in feature of the web server. This software is used both for searching in the database and for navigating the profession and subject vocabularies.

3 Harvesting

3.1 Harvesting Software

The Studera.NU uses the Combine Harvester.¹⁹ More information on how to operate that software can be found in its User's Guide.²⁰ The text presented here is an adaptation of the current README²¹ coming with the distribution. For detailed information on the internals of the Combine, please refer to the technical guide.²² Beware, though, that some parts of the Tech Guide is obsolete.

3.1.1 System Requirements

- The Combine should run on just about any UNIX or clone. It is tested on Linux version 1.2 (or higher), or Solaris 2.5 (or higher)
- Perl version 5.003 (or higher) with MD5 and libwww packages

¹⁷ Zebra Server - Administrators's Guide and Reference
<http://www.indexdata.dk/zebra/zebra.php>

¹⁸ not:ZAP

¹⁹ The Combine Harvesting Robot
<http://www.lub.lu.se/combine/>

²⁰ Combine User's Guide
<http://www.lub.lu.se/combine/docs/uguide.html>

²¹ The Combine README
<http://www.lub.lu.se/combine/dist/README-v1.1.txt>

²² Yong, Tsao: Combine: A Distributed Open System Architecture for WWW Resource Harvesting and Indexing System

<http://www.lub.lu.se/combine/docs/uguide.html>

- To compile combine yourself, you will also need Barkley DB version 2.x as well as g++. Please note that the Berkeley DB 3.x contains changes to the API and will unfortunately not work.

The installation is already available. Upgrades can be obtained from the Combine web site, and will contain any information needed for installing the package and Makefiles for building the distribution.

The Studera.NU is using two harvester installations, one for metadata and course information, the data used in the current service, and another one for supplementary information which may be interesting for students (housing, financing, restaurants, whatever). The latter is currently not used in the public service.

The two installations live in:

```
afrodite.hsv.se:/usr/local/studera_combine/studieinfo
afrodite.hsv.se:/usr/local/studera_combine/kringinfo
```

respectively

3.1.2 Operation overview

It is recommended to read at least the *Overview* section in the user guide ²³ before continuing reading this document.

3.1.2.1 Scheduler SD

The scheduler holds a list of JCFs. A JCF is a URL combined with information about where to send the harvested page and whether this page has been harvested before and if so when, and when it was last modified etc. The scheduler also ensures that a single server is not queried more than once a minute, and that the same page is not fetched more than once a month. To load new URLs into the scheduler they must be converted into JCFs, this is done by bin/jcf-builder.pl. The scheduler uses two database-files db/recycle.db and db/guard.db.

3.1.2.2 Robot-rule daemon

The rrd holds the parsed robots.txt files from each server. The harvester program checks each URL against this database before fetching a page. Rrd uses one database file, db/rrd.db.

3.1.2.3 Receive daemon RD

The RD just receives pages from the harvesters and stores them in the href / directory, where they will be picked up by the parsers.

²³ Combine User's Guide

<http://www.lub.lu.se/combine/docs/uguide.html>

3.1.2.4 Harvesting database proxy: IDBD

The IDBD manages a database that holds information for every URL in the harvester database. Since the files in the harvester database are stored according to the MD5 check sum, the IDBD also contains a mapping from URL to MD5. The IDBD is also a much faster way to for instance find all URLs in the harvest database, instead of having to traverse the entire file-hierarchy of the harvest database.

3.1.2.5 Main programs

harvester.pl

The harvester gets a JCF from the scheduler, checks it with the rrd and then fetches the page. The result is sent to RD.

parser.pl

The parser picks up a file in the href/ directory, parses it and extract links etc. It then updates the IDBD and the harvest database (hdb/)

3.1.2.6 Important utilities

bin/sd-ctrl.pl

is used to start, stop and check the content of the scheduler, as well as changing the scheduling algorithm

bin/sd-load.pl

loads JCFs into the scheduler

bin/jcf-builder.pl

creates JCFs from URLs

bin/new-url.pl

takes all new URLs found by the parsers (since you last ran new-url.pl) and prints them to stdout as well as to log/url."timestamp".new

bin/selurl.pl

filters a list of URLs according to the rules in etc/config_allow and etc/config_exclude. This program implements the Studera.NU harvesting policies. See below.

bin/idb2hrs.pl

dumps the IDBD into hrs/idb.hrs. This file can then be used to reload all URLs into the scheduler among other things.

bin/list-hdb.pl

The same as the previous, except that this uses the harvest-database file hierarchy to produce the file hrs/hdb.hrs. This takes a long time unless the database is small.

bin/hrs2jcf.pl

creates JCFs from a hrs-file created by either one of the two programs above.

3.1.2.7 Examples

Please find below the commands needed for making various operations on the database. Below you will find the actual scripts where such commands are put together for running the Studera.NU harvesting service.

To take the new URLs found by the parsers and load them into the scheduler:

```
bin/new-url.pl | bin/jcf-builder.pl | bin/sd-load.pl
```

If you want to filter using selurl.pl:

```
bin/new-url.pl | bin/selurl.pl | bin/jcf-builder.pl | bin/sd-load.pl
```

Obviously, in the Studera.NU harvesting service these are run automatically using the cron daemon.

3.1.2.8 Running the Robot

The CABIN and the HDB below are two classes of functions in the robot. The former refer to the operation of the harvesters, the handling of the robot rules, the harvesting policies etc and the latter the all the functions associated with the harvesting database.

CABIN and HDB also refers to the locations of these functions on the disk of your computer. In Studera.NU are functions are performed by a single machine, but in larger installations they may be distributed across several machines. In Studera.NU these two directories are the same.

Start CABIN:

Go into CABIN directory and run "bin/start-cabin" This script starts three daemons (scheduler, robot-rule, and tellogd).

Start HDB:

Go into HDB directory and run "bin/start-hdb" This script starts 2 parsers and two daemons (idbd and rd). (you may run any number of parsers)

Start HARVESTER:

Go into HARVESTER directory and run bin/start-harvester This script starts a number of harvesters with their names. You may start as many harvester.pl as you want.

Start SD:

Since SD is closed at starting time, you must open it before loading. Run bin/sd-ctrl.pl open

Loading a list of URLs into SD

```
cat url.lst | bin/jcf-builder.pl | bin/sd-load.pl
```

Stop the robot:

bin/sd-ctrl.pl close This will stop any further harvesting until you re-open the scheduler.

Pausing the system:

bin/sd-ctrl.pl pause will prevent harvesters from getting any further JCFs from the scheduler, this has the same effect as sd-ctrl.pl close, except that the scheduler is still available for loading new JCFs or querying the content.

Kill all:

Run "bin/stop-all". Use this before you shutdown your computer, to make sure that the database-files are consistent.

3.1.2.9 Files**New URLs:**

New URLs extracted from HTML pages by parsers are logged in a number of log files called `log/NEW-URL#n.log` where n is the name you used when starting the parser.

Tellog files:

You can find various log files in `tellog/` directory. The level of logging is controlled by the environment variable `COMBINE_LOGLEV`. If it's set to 0 (or not set at all) the only thing logged are HTTP response-codes that combine doesn't know how to handle, and URLs that are unavailable at the moment (`tellog/UNAVAILABLE.tellog`). Look at the code in `parser.pl` and `harvester.pl` to see what different log levels do. Any JCFs discarded because of too many failed attempts will be logged in `tellog/AUTO_DELETED.tellog`.

3.1.2.10 Databases:

There are two directories for databases: "CABIN/db" and "HDB/db". On Studera.NU they can be found in the same directory:

```
afrodite.hsv.se:/usr/local/studera_combine/studieinfo
```

3.1.2.11 Configuration files:

The main setup file is `etc/combine.conf`. The current configuration can be obtained from the robot itself by running `bin/echo-config.pl`

There are also a few other config-files in `etc config_parsable` : the mime-types the parser can handle (you normally shouldn't change this) `config_binext` : the extensions that will make the harvester do a HEAD request to get the mime-type before it does a GET (if the mime-type is in `config_parsable`) Add or remove extensions here as you wish. `config_allow` & `config_dissallow`: These are control-files for the `selurl.pl` utility, which is a filter to select the URLs to feed into the scheduler. NOTE : the rules in this file are Perl regular expressions, so remember to escape characters like ".".

3.1.2.12 Harvesting Database:

The root of the tree of the harvesting database is `hdb` This directory hierarchy contains all the harvested records, one in each file. The files are named after the MD5 check sum of the corresponding web-page.

3.1.2.13 The parsers spool area: Temp for HRF files

The pages fetched by the harvester are sent to the RD daemon that simply puts them into the HRF files are put in `hrf` directory and will be taken by parsers.

3.2 Harvesting policies

In order to ensure search precision, we have to ensure that the Studera.Nu robot is indexing material about courses and educations, and only that. For that purpose, the robot should be able to identify relevant resources. In addition it should be easy for information providers to publish such materials. Both requirements are ensured by implementing the following rules:

Rule 1. The robot indexes all pages encountered, but stores records only for those containing appropriate metadata.

This simplifies the maintenance the pages to be indexed, since the robot will therefore navigate the resources the same way as ordinary users. There is no need for supplying lists of URLs to indexed.

Rule 2. Robot obeys the robots.txt standard.

A thorough treatment of the robots exclusion standard²⁴ and what it is good for²⁵ is beyond the the scope of this article. The robots.txt equips web masters and information architects with a powerful tool managing how their resources should be presented by search engines.

Rule 3. The Studera.Nu robot is only spidering a predefined URL space.

Like any other harvesting bot, the Studera.Nu robot is “surfing by clicking”, and it communicates with web servers in exactly the same way as does your browser. The robot must know where to get things, and it does so by extracting links from retrieved web pages, but when clicking away, it first checks that the links are inside the URL space.

3.2.1 The URL space concept in Studera.Nu

The permissible URL range is defined by two lists of URL patterns, given as Perl regular expressions.²⁶ These two lists are²⁷

`config_allow`

URL patterns that form the permissible base

`config_exclude`

URL ranges which are to be excluded, in spite of the fact that they are situated inside the URL range defined by the `config_allow` list.

Compare Fig. 1.

The simplest case is the matching of right truncation of URLs. Thus we can “allow” and “exclude” directories on the server `www.hogskolan.se` by

`www.hogskolan.se/utbildningar/`

²⁴ A Standard for Robot Exclusion.

<http://www.robotstxt.org/wc/norobots.html>

²⁵ The Noble Art of Being Indexed or the Webmaster’s Guide to Harvesting Robots
http://nwi.lub.lu.se/web_masters_guide.html

²⁶ perlre - Perl regular expressions
<http://www.perl.com/pub/doc/manual/html/pod/perlre.html>

²⁷ Combine User’s Guide
<http://www.lub.lu.se/combine/docs/uguide.html>

This makes all web pages or scripts residing below `utbildningar/` accessible for the robot. There might be a further directory:

`www.hogskolan.se/utbildningar/internt_larare/`

which may be excluded from harvesting by a “exclude”-rule. These rules may be used on any level, and may include individual file names or scripts. For example we may “allow” (or “exclude”) all material from the script:

`www.hogskolan.se/utbildningar.asp`

if putting this in the appropriate list. If this script is allowed, then all URLs containing it will be allowed. For instance:

`www.hogskolan.se/utbildningar.asp?nasty=rubbish`

Would be harvested

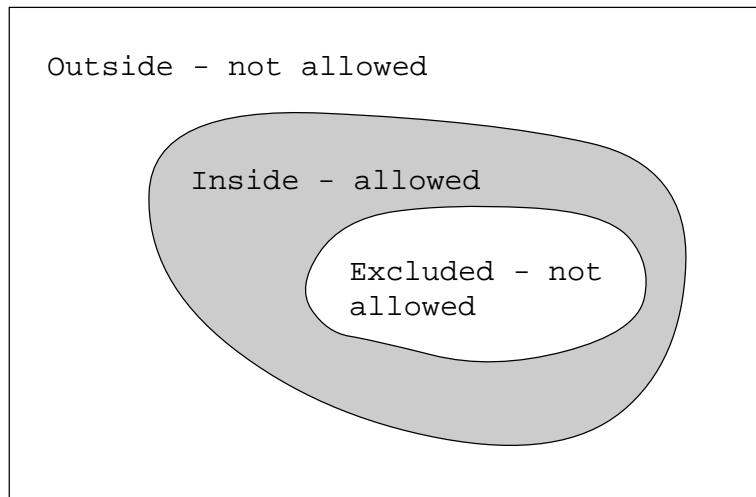

Fig. 1. The total URL space, with the permissible space as a sub-set. The set of excluded URLs is a “hole” in the permissible URL space.

Studera.NU robot’ URL space is not continuous, neither do there exist links to all material. As a consequence, content providers must supply Studera.NU with a single or a couple starting points from which all material is reachable by following links.

Typical setup is start at URL

`http://www.hogskolan.se/utbildningar/index.html`

and follow all links subject to the constraint that they should live within:

www.hogskolan.se/utbildningar/

4 Maintenance practices

Hardly any manual work, other than monitoring, is done in the service. As regards the harvesting database, it is currently built and maintained using the following scheduled activities:

Activity	Schedule (see crontab manual page for notation)
Reindex — Incremental update of search engine index files. Done twice an hour, except during night.	10,40 0-4,6-23 * * *
Total reindex — All index-files are removed, and new fresh indices are created. Done early mornings.	10 5 * * *
Reharvest — Recirculate URLs found during the last half hour. Twice an hour.	50,20 0-4,6-23 * * *
Big reload — The robot revisits all pages every second day.	10 0 * * 1,3,5
Big retry — Robot revisits all starting points and all URLs extracted during the last fortnight, that have not been included in the harvesting database.	10 0 * * 0,2,4,6

The scripts performing the jobs are collected in the directory `afrodite.hsv.se:/usr/local/studera_combine/studieinfo/cron/`. The current ones are included in Appendix D.

kurser,Ändringar Distansutbildning Sommarkurser Kväll- och
Deltidskurser Utlandsstudier Studievägledning Funktionshinder
Högskoleprov Antagning Examen Ladok Institutioner Sök utbildningar
Kursen vänder sig till lärare eller blivande lärare, som vill
lära sig mer om geometri och statistik. I geometridelen av kursen
ingår plangeometri, rymdgeometri och Icke-Euklidisk geometri, i
statistikdelen ingår både statistik och sannolikhetslära. Kursen har
en tydlig didaktisk inriktning med många övningar och laborationer. I
båda momenten ingår datorövningar. Sammankomster för distanskurs:
Tillgång till dator med Internetanslutning krävs. Förkunskaper:
Standardbehörighet G.4 ( Förklaring finns här. ) Urvalsregler Övrigt
Tidigare högskolestudier krävs inte. Utbildningsnivå: 1 - 20
poäng. Mer information Om kursen: www.tnv.mh.se/mfs Om MATEMATIK

8 Appendix D. Scripts for scheduled activities

8.1 Big reload

```
#! /usr/local/bin/bash
PATH=.:./bin:/usr/bin:/usr/local/bin
export PATH;
cd /usr/local/studera_combine/studieinfo
bin/export-netto.pl
bin/sd-ctrl.pl pause
bin/selurl.pl hrs/idb.hrs | bin/jcf-builder.pl | bin/sd-load-force.pl
bin/sd-ctrl.pl open
cd /usr/local/studera_combine/studieinfo/log
clean.pl
```

8.2 Big retry

```
#! /usr/local/bin/bash
PATH=.:./bin:/usr/bin:/usr/local/bin
export PATH;
cd /usr/local/studera_combine/studieinfo
bin/export-netto.pl
bin/sd-ctrl.pl pause
cat log/url.* | sort -u | bin/selurl.pl | bin/url2jcf.pl | bin/sd-load
bin/sd-ctrl.pl open
cd /usr/local/studera_combine/studieinfo/log
clean.pl
```

8.3 Reharvest

```
#! /usr/local/bin/bash
PATH=.:./bin:/usr/bin:/usr/local/bin
export PATH;

cd /usr/local/studera_combine/studieinfo
bin/idb2hrs.pl
bin/sd-ctrl.pl pause
```

```
bin/new-url.pl | bin/selurl.pl | bin/url2jcf.pl | bin/sd-load.pl
bin/sd-ctrl.pl open
```

8.4 Reindex

```
#! /usr/local/bin/bash

PATH=/bin:/usr/local/bin:/usr/bin
export PATH;

cd /usr/local/studera/zebra
run_zebraidx &
```

8.5 Total reindex

```
#! /usr/local/bin/bash

PATH=/bin:/usr/local/bin:/usr/bin
export PATH;

cd /usr/local/studera/zebra
rm DB/*
run_zebraidx &
```

10 Revision log

```
$Log: index_base.html,v $
Revision 1.4  2001/09/25 18:30:39  siglun
Added most information needed for understanding the Z39.50
server.

Revision 1.3  2001/09/25 12:46:23  siglun
Included long section on maintaining the robot.

Revision 1.2  2001/06/14 10:33:05  siglun
Preliminary plan of the report ready

Revision 1.1  2001/06/13 07:08:56  siglun
Initial revision
```
